AI Native Sales-Cycle Control

Deals rarely die loudly. They go quiet. This reads a deal's entire note history, tells you whether it is actually still moving, and explains why in plain English.

Open deal

Momentum read. Healthy, stalling, or at risk.

Lost deal

Post-mortem. Final, or one objection worth revisiting.

Won deal

Win analysis. What closed it, and what repeats.

// the problem

The expensive deals are the quiet ones

Pipeline review catches the deals someone remembers to raise. It rarely catches the one that has not really moved in six weeks. There is no bad news to report and nothing to mark lost, so it sits in the forecast at full value while everyone assumes somebody else is on it.

By the time a quiet deal surfaces, the useful window has closed. Nobody was negligent. The signal was spread across forty notes and eleven months, and no one had time to read them.

// what it does

A verdict, not a summary

It reads a deal's whole note history and returns a judgement on whether the deal is still moving, together with the reasoning that produced it. A summary tells you what was said. This tells you what it means, and shows its working so a rep can push back on it.

It weighs how long since the last touch, whether recent notes show forward motion or stalling language, and how that compares with the deal's own earlier trajectory.

// three questions, not one

What it asks depends on where the deal stands

A single "summarise this deal" prompt wastes the most useful thing you already know: the deal's status. Three questions, three schemas, dispatched automatically.

Open deal

Momentum read

Healthy, stalling, or at risk, with the reasoning that led there.

Lost deal

Loss post-mortem

Confirms the loss was final, or names a specific unaddressed objection worth revisiting. Closed-lost is usually treated as an archive. Often it is a list of deals that stalled on one objection nobody went back to.

Won deal

Win analysis

What pattern actually closed it, and which part of that is repeatable on the next one.

```
// why it is not a chatbot wrapper
```

The easy version of this does not work

The easy version pastes a deal's notes into a prompt and prints whatever comes back. It reads well and tells you nothing, because a model asked an open question about sales notes will agree with whatever tone those notes happen to carry.

This returns a **structured status plus a short reasoning string** against a fixed schema, so every answer is checkable rather than merely plausible. When a verdict is wrong you can see which signal it read wrong. That is the difference between a tool a sales team keeps using and a demo they try twice.

```
// built for real cycles
```

Tested against deals that look like yours

Seed data includes two enterprise-scale deals modelled on multi-quarter B2B cycles: **more than 50 timestamped notes each, spanning over a year**, with champion departures, stalled quarters and recoveries included.

Momentum reasoning either works on a messy year-long deal or it does not work at all. A five-note demo proves nothing.

```
// stack
```

Next.js

TypeScript

Supabase

PostgreSQL

Row Level Security

Anthropic API

Structured tool use

Tailwind CSS

```
// status
```

Built in public, phase by phase

Auth, core CRUD, the AI insight feature and the seed data are live now. Every commit ships a working, demoable state, so what you see is what runs.

See it on a real deal

Log in as the demo account and run **Analyze** on the seeded deals, including the two enterprise-scale cycles.
